

Natural Flood Management in the Upper Coln

Timelapse photos of water being held back by Leaky Woody Debris Dams after high rainfall, showing how NFM can not only help slow the flow but provide additional habitat for wildlife.

Photo of Soil Bunds holding back water. The aim of these are to intercept the water and store it temporarily, to reduce the impact of high rainfall downstream.

Photos of FWAG Staff helping with Tree planting. Tree planting can benefit so much more than just carbon capture. A well thought out and carefully designed woodland can also provide a great range of habitats for wildlife, help improve water quality by reducing soil erosion and filtering out sediment and also slow the flow of water across the land which, together with a range of other interventions, can help to reduce flooding downstream.
